GP5 – Sprint 1 Report

Project: Master's Auto Detail Website Redesign
Team: Team VARdrid
Methodology: Agile
Sprint: Sprint 1

GP4 Approval Confirmation

Before we started building anything, our Product Owner approved our Sprint Plan from GP4. That plan outlined what we wanted to complete in Sprint 1, mainly focusing on building the first version of the website with basic structure and key features. Once we had that approval, we moved into development.

Sprint 1 Goal

The goal of this sprint was to create a working version of the redesigned website. We wanted something functional that users could actually interact with, not just a mockup. The focus was on making it easier for customers to find services, understand pricing, and contact the business.

Part 1: Development / Configuration Progress

This week, we built the website from scratch using HTML, CSS, and a little bit of JavaScript. Instead of just planning, we actually created a real, working site and got it live using GitHub Pages.

Here's what we worked on:

Homepage redesign:
We created a new homepage with a clear headline ("Get that showroom feeling all over again") and strong call-to-action buttons like "Call Now" and "Request a Quote." The goal here was to immediately show users what the business offers and push them toward taking action.

Navigation structure:
We added a navigation bar that includes sections like Auto Detailing, Individual Services, Ceramic Coatings, Basic Detail, Full Detail, Sizing Guide, and Contact. This makes it way easier for users to find what they're looking for instead of scrolling through everything.

Pricing tables:
We built out tables for both Basic Detail and Full Detail services. The pricing is organized by vehicle size, which makes it easier to compare options. This helps solve one of the main problems from earlier: customers not understanding pricing.

Vehicle sizing guide:

We added a sizing chart that shows what counts as small, medium, large, etc. For example, trucks fall under “Large” and vehicles like a Chevy Tahoe are “Extra Large.” This helps users figure out their pricing category without having to call.

Quote request form:

We added a form where users can enter their info, vehicle size, service type, and preferred date. This gives customers another way to contact the business instead of just calling, which should help reduce unnecessary phone calls.

Mobile responsiveness:

We made sure the site works on mobile by adding a menu button and adjusting the layout. This is important since a lot of users will probably visit the site from their phones.

Technical Tools and Platforms Used

We used basic web development tools, including ChatGPT, HTML, CSS, and JavaScript, to build the site. We used GitHub to manage the files and GitHub Pages to publish the site so it’s actually live and accessible online. This allowed us to create a real working product without needing to pay for hosting.

Challenges and How We Solved Them

One issue we ran into was design and readability. When we switched to a black and red color scheme, some text became hard to see. We fixed this by adjusting the colors and contrast so everything is readable.

Another challenge was accidentally losing parts of the website during development. We solved this by rebuilding the full version and making sure everything was saved properly before uploading it again.

We still need to connect parts of the site to actual payment methods, correct email, and other tweaks.

Part 2: Deliverable Demonstration

We now have a working website prototype that includes:

- Homepage with call-to-action buttons
- Service sections and descriptions
- Pricing tables
- Vehicle sizing guide
- Quote request form
- Contact section

We also successfully deployed the site using GitHub Pages, which means the prototype is live and can be accessed through a public URL. https://kbonn28-arch.github.io/masters-auto-detail-site/

Part 3: Partner Feedback

Based on earlier feedback, one of the main issues was that customers had trouble understanding services and pricing. Our redesign directly addresses that by making pricing clearer, adding structure, and improving navigation.

Moving forward, we plan to continue improving the site based on additional feedback, especially around visual design and adding real images.

Sprint Retrospective

What went well:

- We successfully built and deployed a real working website
- The layout is much clearer and easier to use
- We completed all major Sprint 1 goals

What could be improved:

- The design could look more polished with real images and branding
- The form is not fully functional yet (needs to be connected)

Next steps (Sprint 2):

- Connect the form so it actually sends submissions
- Add real images and branding
- Improve visual design to better match the real business
- Possibly add Google Maps integration

Part 5: Supporting Evidence (APA)

Textbook Alignment (Service Standardization & IT Value):

According to McKeen and Smith (2022), IT initiatives provide the most value when they simplify complex business processes and make them "measurable and linked to business outcomes" (p. 145). By developing the Vehicle Sizing Guide and categorized Pricing Tables, the team has standardized the "Request a Quote" process. This directly addresses the business problem of "repetitive customer phone calls" by providing immediate clarity on service costs. This implementation follows the principle of IT Value Realization, where the technology acts as a filter to ensure that the inquiries reaching the business owner are higher-quality leads who already understand the pricing structure.

Industry Evidence (UX Design and Conversion):

The inclusion of a "Mobile-First" responsive layout and clear Call-to-Action (CTA) buttons (e.g., "Request Quote" and "Call Now") aligns with industry best practices for local service businesses. According to Atlassian's Agile standards, delivering a Minimum Viable Product (MVP) that focuses on core user "Action Paths" allows for faster validation of the solution. By launching these features in Sprint 1, the team can begin gathering real-world data on user interaction patterns, ensuring that future optimizations in Sprint 2—such as the Maintenance Club landing page—are built on a stable and user-tested foundation.
